# Finding Maxima and Minima of DiffEq Solutions

### Chris Rackauckas

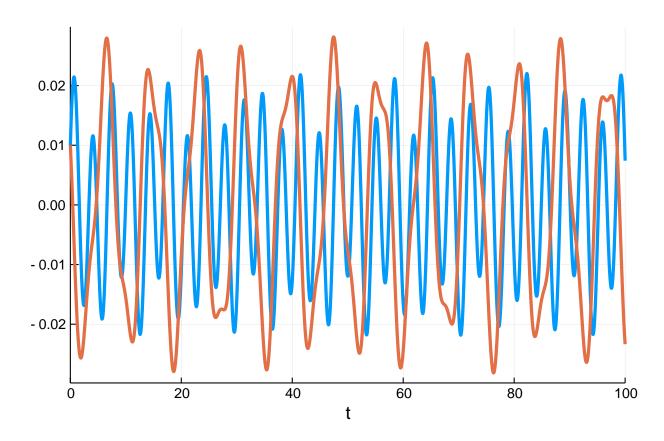

June 26, 2019

#### 0.0.1 Setup

In this tutorial we will show how to use Optim.jl to find the maxima and minima of solutions. Let's take a look at the double pendulum:

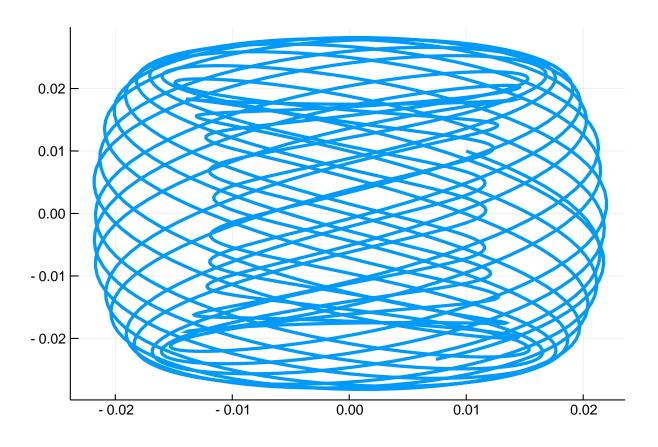

```
#Constants and setup
using OrdinaryDiffEq
initial = [0.01, 0.01, 0.01, 0.01]
tspan = (0.,100.)
#Define the problem
function double pendulum hamiltonian(udot,u,p,t)
    \alpha = u[1]
    1\alpha = u[2]
    \beta = u[3]
    1\beta = u[4]
    udot .=
    [2(1\alpha - (1+\cos(\beta))1\beta)/(3-\cos(2\beta)),
    -2\sin(\alpha) - \sin(\alpha+\beta),
    2(-(1+\cos(\beta))1\alpha + (3+2\cos(\beta))1\beta)/(3-\cos(2\beta)),
    -\sin(\alpha+\beta) - 2\sin(\beta)*(((1\alpha-1\beta)1\beta)/(3-\cos(2\beta))) + 2\sin(2\beta)*((1\alpha^2 - 2(1+\cos(\beta))1\alpha*1\beta))
    + (3+2\cos(\beta))1\beta^2/(3-\cos(2\beta))^2
end
#Pass to solvers
poincare = ODEProblem(double_pendulum_hamiltonian, initial, tspan)
ODEProblem with uType Array{Float64,1} and tType Float64. In-place: true
timespan: (0.0, 100.0)
u0: [0.01, 0.01, 0.01, 0.01]
sol = solve(poincare, Tsit5())
retcode: Success
Interpolation: specialized 4th order "free" interpolation
t: 193-element Array{Float64,1}:
   0.0
   0.08332584852065579
```

 [0.00421143, -0.0299109, 0.0187506, -0.0156505]
 [0.00574124, -0.0416539, 0.00741327, -0.023349]
In time, the solution looks like:
using Plots; gr()
plot(sol, vars=[(0,3),(0,4)], leg=false, plotdensity=10000)
```

while it has the well-known phase-space plot:

plot(sol, vars=(3,4), leg=false)

#### 0.0.2 Local Optimization

Let's fine out what some of the local maxima and minima are. Optim.jl can be used to minimize functions, and the solution type has a continuous interpolation which can be used. Let's look for the local optima for the 4th variable around t=20. Thus our optimization function is:

```
f = (t) -> sol(t,idxs=4)
#1 (generic function with 1 method)
```

first(t) is the same as t[1] which transforms the array of size 1 into a number. idxs=4 is the same as sol(first(t))[4] but does the calculation without a temporary array and thus is faster. To find a local minima, we can simply call Optim on this function. Let's find a local minimum:

```
using Optim
opt = optimize(f,18.0,22.0)

Results of Optimization Algorithm
 * Algorithm: Brent's Method
 * Search Interval: [18.000000, 22.000000]
 * Minimizer: 1.863213e+01
 * Minimum: -2.793164e-02
 * Iterations: 11
 * Convergence: max(|x - x_upper|, |x - x_lower|) <= 2*(1.5e-08*|x|+2.2e-16): true
 * Objective Function Calls: 12</pre>
```

From this printout we see that the minimum is at t=18.63 and the value is -2.79e-2. We can get these in code-form via:

```
println(opt.minimizer)

18.632126799595834

println(opt.minimum)

-0.027931635264246277
```

To get the maximum, we just minimize the negative of the function:

```
f = (t) -> -sol(first(t),idxs=4)
opt2 = optimize(f,0.0,22.0)
```

```
{\tt Results} \ {\tt of} \ {\tt Optimization} \ {\tt Algorithm}
```

\* Algorithm: Brent's Method

\* Search Interval: [0.000000, 22.000000]

\* Minimizer: 1.399975e+01 \* Minimum: -2.269411e-02

\* Iterations: 13

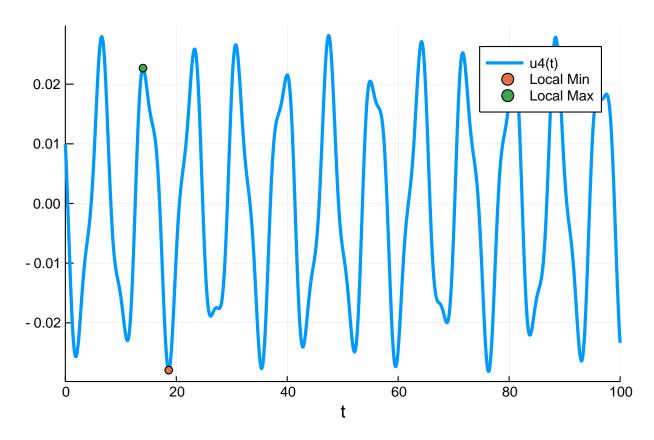

\* Convergence:  $max(|x - x_upper|, |x - x_lower|) \le 2*(1.5e-08*|x|+2.2e-16)$ 

): true

\* Objective Function Calls: 14

Let's add the maxima and minima to the plots:

```
plot(sol, vars=(0,4), plotdensity=10000)
scatter!([opt.minimizer],[opt.minimum],label="Local Min")
scatter!([opt2.minimizer],[-opt2.minimum],label="Local Max")
```

Brent's method will locally minimize over the full interval. If we instead want a local maxima nearest to a point, we can use BFGS(). In this case, we need to optimize a vector [t], and thus dereference it to a number using first(t).

```
f = (t) -> -sol(first(t),idxs=4)
opt = optimize(f,[20.0],BFGS())
```

Results of Optimization Algorithm

\* Algorithm: BFGS

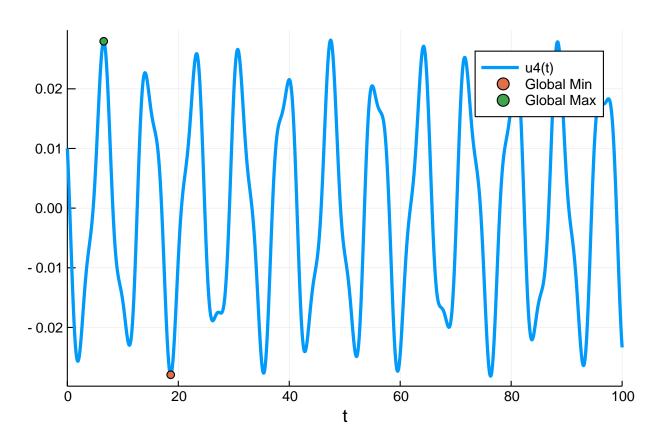

\* Starting Point: [20.0]

#### 0.0.3 Global Optimization

If we instead want to find global maxima and minima, we need to look somewhere else. For this there are many choices. A pure Julia option is BlackBoxOptim.jl, but I will use NLopt.jl. Following the NLopt.jl tutorial but replacing their function with out own:

```
import NLopt, ForwardDiff
count = 0 # keep track of # function evaluations
function g(t::Vector, grad::Vector)
 if length(grad) > 0
   #use ForwardDiff for the gradients
   grad[1] = ForwardDiff.derivative((t)->sol(first(t),idxs=4),t)
 sol(first(t),idxs=4)
opt = NLopt.Opt(:GN_ORIG_DIRECT_L, 1)
NLopt.lower_bounds!(opt, [0.0])
NLopt.upper_bounds!(opt, [40.0])
NLopt.xtol_rel!(opt,1e-8)
NLopt.min_objective!(opt, g)
(minf,minx,ret) = NLopt.optimize(opt,[20.0])
println(minf," ",minx," ",ret)
-0.027931635264246215 [18.6321] XTOL_REACHED
NLopt.max_objective!(opt, g)
(maxf,maxx,ret) = NLopt.optimize(opt,[20.0])
println(maxf," ",maxx," ",ret)
0.027968571933041936 [6.5537] XTOL_REACHED
plot(sol, vars=(0,4), plotdensity=10000)
```

```
scatter!([minx],[minf],label="Global Min")
scatter!([maxx],[maxf],label="Global Max")
```

## 0.1 Appendix

This tutorial is part of the DiffEqTutorials.jl repository, found at: https://github.com/JuliaDiffEq/DiffEqTo locally run this tutorial, do the following commands:

```
using DiffEqTutorials
DiffEqTutorials.weave_file("ode_extras","03-ode_minmax.jmd")
```

Computer Information:
